## Abstract

Newly independent Republic of Moldova joined the World Bank and the IMF in 1992. The World Bank designated it a 'middle income' country, a status it retained for Bretton Woods lending until 1997. The middle income designation implied that the government of Moldova was not eligible for concessionary finance from the multilateral and major bilateral development agencies. After demonstrating that assigning middle income status to Moldova was a mistake, this article investigates the consequences. A simple procedure is used for calculating counterfactual scenarios of Moldova being assigned low income status in the early 1990s. The counterfactual scenarios suggest that the development and welfare costs of the mistake were extremely high: a much greater fall in income per capita than would otherwise have been the case, with associated increases in headcount poverty and lower life expectancy. Had Moldova been designated a low income country in the early 1990s, by the mid-2000s it would have been a middle income country instead of the poorest in Europe.

## Keywords

central Europe, economic development, poverty, World Bank

## 1. Introduction

In 1992 Moldova joined the World Bank and the International Monetary Fund (IMF), and was assigned to middle income status by the World Bank.<sup>1</sup> For developing country governments, the distinction between low income and middle income status is of great practical importance. To be defined a low income country by the World Bank gives a government access to concessional finance. This means access to (1) the International Development Association (IDA), the World Bank's 'concessional window'; (2) several

IMF concessional funds (for example, the Poverty Reduction and Growth Facility); (3) IDA terms for debt restructuring; and, in practice, (4) concessional lending and grants from bilateral agencies.<sup>2</sup> As a result of the decision by the World Bank on its income level, Moldova found it necessary to borrow on the private commercial capital market and on terms close to commercial ones from the World Bank, IMF and regional development banks.<sup>3</sup>

If one accepts the dichotomy between low and middle income as a valid basis for determining the terms for development finance, then one must accept that errors of measurement can result in inequities and inconsistencies near the borderline that divides the two groups. However, the case of Moldova was much more serious than this. In Section 2 it is demonstrated beyond reasonable doubt that the World Bank made a mistake when it assigned Moldova to the middle income category. It is also demonstrated that the European Bank for Reconstruction and Development (EBRD) and the IMF assigned Moldova a per capita income well below the World Bank low income borderline as early as 1994, and it was not until 1999 that the World Bank officially shifted Moldova from the middle to low income category.

It is beyond dispute that low income status brings economic benefits to a country, and equally beyond dispute that being assigned to middle income status would have concrete economic costs. In Section 3 a simple national income accounting model is used to estimate the cost to Moldavians of the World Bank's miscalculation of its national income. In Section 4 the output costs associated with the erroneous middle income designation are used to calculate the impact on social indicators. Section 5 considers the budgetary effects, and especially during the severe deficit reduction measures of 1997–9. The final section re-emphasizes the case for financial compensation for Moldova's mistaken identity.

## 2. Moldova's per capita income

In the early 1990s, the Bretton Woods institutions encountered a unique challenge which would not be repeated: establishing the procedures and policies for initiating operations in countries that would transit from central planning to market regulation. The policies applied to these countries, reinforced by strict conditionalities, would prove extremely controversial and be associated with economic contraction in all transition countries and collapse in more than a few (see Weeks et al., 2005: Ch. 2). An apparently administrative issue, but in practice of overwhelming importance, was the valuation of the national products of the countries. This valuation would determine the terms on which governments could borrow, and be central to the extent to which they would have access to bilateral development assistance.

A World Bank research paper in 1992 sought to create a rigorous analytical framework for a concordance between the administered prices of the planning system and the market evaluation of those goods and services. It would appear that these estimates were the basis for the first listing of the former Soviet Union countries in the *World Development Report 1993* (World Bank, 1993b).<sup>4</sup> That research report gives the per capita income of Moldova as US\$2360. Table 4 of the report compares this to 10 other estimates for Moldova, all of which were lower, on average by 19%, the lowest being 36% smaller (World Bank, 1992: 20).<sup>5</sup> At the very least, one can say that the estimates of Moldova's

GDP at independence were approximate and subject to reinterpretation, as they would be by the World Bank in the late 1990s.

Table 1 reports various estimates of Moldova's per capita income,<sup>6</sup> from the World Development Reports, the World Bank country reports for Moldova, the EBRD, the IMF and the National Bank of Moldova. The last column gives the per capita income of the lowest middle income country for each *World Development Report* (1993 to 1995) or the low income borderline (after 1995). The second column, 'WDR 93', begins with the per capita income figure in WDR 1993 and adjusts it using annual growth rates.<sup>7</sup> Comparison of the first two columns suggests that the World Bank substantially revised Moldova's per capita income at least twice, in 1993 and 1997 (in the former year by 30% compared to what the 1991 value and growth rates imply, and in the latter year by almost half).

Since the contentious issue is when these statistics were assigned, one should note that the WDR numbers appeared with a two-year lag (e.g. 1991 in the 1993 report), the World Bank country paper values were contemporary, the EBRD in mid-1995, the IMF in 1996 and the National Bank of Moldova assigned the 1993 number in 1995. The table demonstrates beyond challenge that by mid-1995, two international organizations, the EBRD and the IMF, accepted a per capita income of Moldova that qualified it as a low income country.

This date is important, because major lending to Moldova by the IMF would begin in late 1995,<sup>8</sup> and the World Bank would make over 50% of its lending after 1995. Almost all of the loans by both multilaterals would be non-concessional.<sup>9</sup> The EBRD would begin its lending in 1995, also non-concessional.<sup>10</sup> Thus, the two organizations that in their official documents reported a per capita income well below the low income country

**Table 1.** Various statistics on Moldova's per capita income, 1991–2000 (US\$ 1995)

1999	370	910	350			321	
2000	379	931				354	

*Notes and sources:* WDR: from the annual and semi-annual *World Development Reports* (two-year lag in title date, so the 1991 figure was published in 1993).

WDR 93 is the time series implied by the 1991 figure, using accepted rates of growth for 1991–2000.

WB CP: the per capita income figures found in the World Bank country reports for 1994 and 2004.

EBRD: from European Bank for Reconstruction and Development (*Transition Report Update* 1995).

IMF: found in IMF (1996).

NBM: from the National Bank of Moldova website.

LY WB: for 1991–5 the per capita income of the lowest middle income country; 1997–8 the official dividing line between low and middle income countries.

borderline would lend to Moldova on middle income country terms. In 1999, when debt service reached 15% of GDP, these three organizations would account for 62% of Moldova's external debt and 70% of public sector debt. Had these loans been on IDA terms, this entire debt would have been within its grace period.<sup>11</sup> Therefore, a closer inspection of the World Bank's reporting on Moldova's per capita income is appropriate.

Table 2 demonstrates the degree of accuracy of the estimates of per capita income by the World Bank for 1991 in seven ex-USSR countries. The countries are Moldova and all other ex-USSR countries that were reported to have per capita income less than Moldova's in 1991. The first column reports the statistic given in *World Development Report 1993*. Under 1997, the lower number is the per capita income assigned to the country in *World Development Report 1998/1999*.<sup>12</sup> The upper row for each country gives the per capita income implied by 'consensus' growth rates for each country.<sup>13</sup> The purpose of the table is to inspect the designation of countries to 'low income' status by the World Bank. The last row of the table gives the lowest per capita income of middle income countries or the benchmark per capita income for low income status.<sup>14</sup> Uzbekistan was not designated as low income in any WDR.

The final column reports the ratio of the per capita income implied by the WDR 1991 statistic and consensus growth rates. The table demonstrates several important points. For only one country, Georgia, does the WDR 1991 statistic generate a 1997 per capita income close to that assigned to it in WDR 1998/1999, though the number for Turkmenistan might be considered within reasonable error of measurement. For the other five countries that became defined as low income, the difference varies from slightly over 40% (Kyrgyz Republic) to 90% (Armenia). The only reasonable conclusion to reach is that the World Bank adjusted downwards the per capita incomes of these countries on some basis for which we have no information.

This adjustment occurred at a different time for each country. For Tajikistan, the adjustment was made for 1992 (by 49%, reported in the WDR 1993); for Armenia in 1993 (by 90%); for the Kyrgyz Republic and Azerbaijan in 1994 (42% and 96%, respectively); and for Turkmenistan and Moldova in 1997 (18% and 86% respectively).<sup>15</sup> There is no obvious reason for some countries benefiting from adjustment earlier than others, which suggests that the adjustments were ad hoc. The practical consequences of later adjustment were profound: lack of access to IDA lending and concessional funds (including grants) from bilateral lenders. In the case of Moldova, and perhaps others, this lack of access resulted in substantial borrowing at commercial rates.<sup>16</sup>

In summary, it is beyond dispute that on the basis of per capita income, Moldova qualified as a low income country in the mid-1990s. The World Bank made a mistake in its estimate of the country's per capita income for 1991, and persisted in this mistake until 1998–9. This was recognized by the IMF and EBRD in 1995, and by implication by the World Bank in its 1998–9 revision of the country's per capita income. It is also beyond dispute that multilateral lending to Moldova, at least by 1995, should have been on IDA terms. Therefore, it follows that through much of the 1990s and into the 2000s, the government of Moldova paid debt service, a considerable portion of which was to the World Bank itself,<sup>17</sup> which was unjustified by the procedures of multilateral lending.<sup>18</sup> Further, the high debt burden caused Moldova to be more affected by the Russian financial crisis of 1998 than other former Soviet countries (Loukoianova and Unigovskaya, 2004: 8, 17, 20). The next section estimates the impact of the World Bank's mistake.

### 3. Counterfactual per capita income scenarios

It should not be controversial that being assigned middle income status rather than being placed in the low income category would have an economic cost.<sup>19</sup> This would result from the opportunity cost of the differential in debt service and foregone concessional assistance grants. This section uses the familiar national income identity to generate counterfactual scenarios that allow the cost to be calculated based on reasonable assumptions.

National income is equal to the sum of private consumption, private investment, government expenditure, net exports and inventory change. The last is assumed to be zero, which is justified over an extended period, though there may be minor errors in any year. Following accepted theory, private consumption is assumed to be a function of disposable income (national income minus government revenue), and imports a function of aggregate income. On these assumptions, the level of national income is equal to the components of autonomous expenditure (investment, government expenditure and exports) times the familiar aggregate multiplier, where the latter is determined by three parameters, the propensities to consume, tax and import (see the Appendix for the algebra).

In the calculations private investment and exports are assumed to be the same in the counterfactuals as in the actual outcome, with public expenditure the only element of

autonomous demand that changes. The calculations do not include counterfactual changes in interest rates, a major determinant of the cost of investment. For exports, the standard assumption is made that their demand is determined externally, and exchange rate effects are ignored. If, as seems reasonable, the absence of a debt burden would raise private expectations and investment, the counterfactuals are conservative in their estimate of the economic cost of middle income status.

The most difficult part of the counterfactual exercise is to determine the shares of the components of autonomous expenditure and government revenue, because different sources report different statistics for some years. Because this study focuses upon the effects of a decision by the World Bank, World Bank statistics were used when sources were in disagreement, or IMF statistics if the World Bank did not report the statistic (see the Appendix for a discussion of data sources, and Appendix Table A2 for the basic statistic used in the counterfactuals).

Three counterfactual calculations are generated, on the assumption that Moldova was assigned low income status in 1994, a year after it joined the World Bank and IMF:

1. *No debt service payments.* If Moldova had been designated a low income country in 1995, debt service in that and subsequent years would have been close to zero. During 1990–4 debt service was less than 1% of GDP in every year, and had the subsequent loans been on IDA terms there would have been a near-zero interest rate and a grace period longer than the counterfactuals calculated in this study. Since it is an unrequited transfer, debt service does not stimulate aggregate demand. Actual aggregate demand increasing public spending is the reported share in GDP minus the share of debt service. The first counterfactual assumes that all debt service becomes domestic expenditure.
2. *No debt service and 'representative' concessionary grants.* As a low income country, Moldova would have received official development assistance (ODA) in grants. While the counterfactual for debt service was simple to formulate, deciding on the hypothetical ODA was more speculative. The assumption was made that Moldova would have received a share of ODA in GDP equal to the average for the low income countries of the former Soviet Union (these statistics are reported in Table A1 in the Appendix). The counterfactual average for Moldova (the second smallest of these countries) is the same as the actual value for Armenia (the smallest country) and over a percentage point below that for the Kyrgyz Republic (third smallest).
3. *Public spending on imports.* The assumption in the second counterfactual that government spending increased by the share of debt service and ODA would imply a relative shift in the distribution of domestic expenditure from the private to the public sector. While the private sector had a high and increasing propensity to import during the 1990s and 2000s, the import share of public expenditure was quite low. Therefore, the expenditure shifting from private to public would reduce the aggregate import propensity and increase the multiplier (see the Appendix for details). The third counterfactual scenario applies this 'adjusted multiplier' to the public spending share in the second counterfactual.

These three counterfactuals can be epitomized as follows:

1. *no debt service*, what if Moldova had received its loans on IDA terms?
2. *no debt service and ODA*, what if Moldova had received its loans on IDA terms and representative ODA levels? and
3. *no debt service and ODA and public expenditure effect on imports*, what if Moldova had received its loans on IDA terms and representative ODA levels, and the import propensity fallen as implied by the increase in government expenditure?

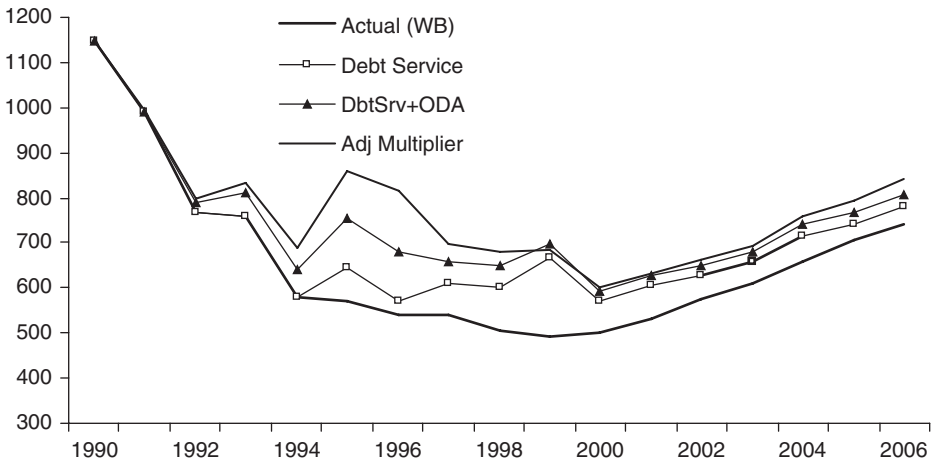

The counterfactuals are shown in terms of per capita income in Figure 1 (with the numbers in Table A2 in the Appendix). It comes as no surprise that all of the counterfactual calculations yield a GDP and GDP per capita above the actual statistic. This follows necessarily since each counterfactual assumes a higher level of aggregate expenditure than actually was realized, and the economy had excess capacity. Table 3 summarizes the difference between the counterfactuals and actual per capita income. In the first half of the 1990s, the difference was relatively small, just 5% on an annual average, with ODA the largest element and debt service zero. For the second half of the decade, the calculated losses are dramatic, over 40% of GDP, with debt service alone making a difference of 17%. Perhaps most striking is the lingering effect of the mistaken identity of Moldova. During 2000–6, well after Moldova had been declared low income, debt service depressed per capita income by 12% per year, and all three counterfactual components reduced it by slightly over 20%.

Credibility is provided for the counterfactual scenarios when one compares Moldova to other low income countries of the former Soviet Union. One of the principle consequences of Moldova's debt burden was to undermine the financial stability of the country. When the Russian financial crisis of 1998 swept the region, Moldova's debt made the country especially vulnerable, as demonstrated in Figure 2. The six countries in the chart in addition to Moldova were selected because they all had low income status by the end of the 1990s. Of the seven countries, Moldova was unique during 1997–2000 in that it had neither low income status nor petroleum.<sup>20</sup> During 1992–7, all seven countries show a similar downward trend in per capita income, and Moldova's decline was *less than* the

**Table 3.** Summary of losses, per capita, annual average (US\$ 1995)

	1990–4	1995–9	2000–6	All years
1. Debt service	0	89	74	57
2. ODA	27	69	33	42
3. Multiplier	16	61	23	32
Total loss	43	218	130	131
Per capita GDP	848	529	618	660
Total loss/actual %	5.1	41.2	21.1	19.8

Notes: Each row refers to the loss calculated in the counterfactual for each item alone. 'Total loss' is the difference between actual values and the third counterfactual.

**Figure 1.** Actual and counterfactual GDP per capita, Moldova, 1990–2006 (US\$ 1995, World Bank)

Notes: Actual is GDP per capita calculated by using the *World Development Report 1997* statistic for per capita income in 1995, multiplied by the World Bank population statistics.

Less Debt service is the autonomous demand multiplier times the components of exogenous expenditure, assuming that public sector external debt service was used as domestic expenditure.

Less DbtSrv + ODA is the previous counterfactual calculation, plus an increase in government expenditure equal to the difference between the official development assistance received by low income former Soviet Union countries and Moldova (percentage of GDP).

Adjusted multiplier is the two previous counterfactuals, with the additional assumption that the increase in government expenditure from debt service and ODA reduces the import propensity.

Sources: See Appendix for data and method of calculation.

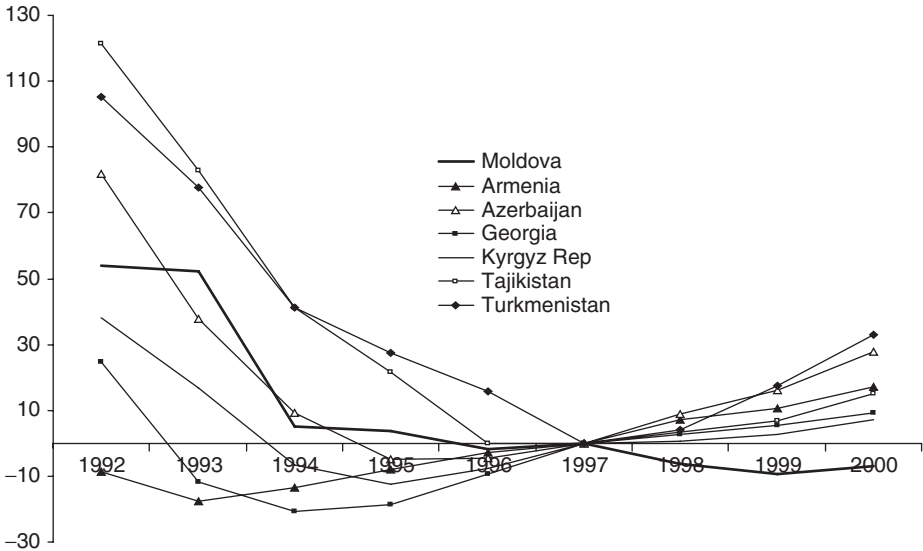

average of the other countries. However, after 1997 only Moldova suffered a decline in per capita income in the wake of the Russian crisis. A simple hypothesis test indicates that if one controls for petroleum exports, being assigned low income status was associated with a per capita income 13% higher than in its absence.<sup>21</sup> This cross-country result is consistent with the analysis above that Moldova bore a heavy cost for the non-concessionary borrowing and lack of development assistance resulting from its middle income status.

If is obvious that the erroneous designation of Moldova to middle income status had an economic cost, it should be equally obvious that the loss of per capita income had a negative impact on social indicators. In the next section, the counterfactual calculations of per capita income are used to generate counterfactual scenarios for key social indicators.

#### 4. Counterfactual social indicator scenarios

If the poor are clustered close below the poverty line, even small declines in per capita income result in a substantial increase in the number of people below that poverty line. In addition, falling per capita income tends to reduce government expenditure per capita.

**Figure 2.** Index of constant price GDP, former Soviet Union low income countries, 1992–2000 (1997 = 0)

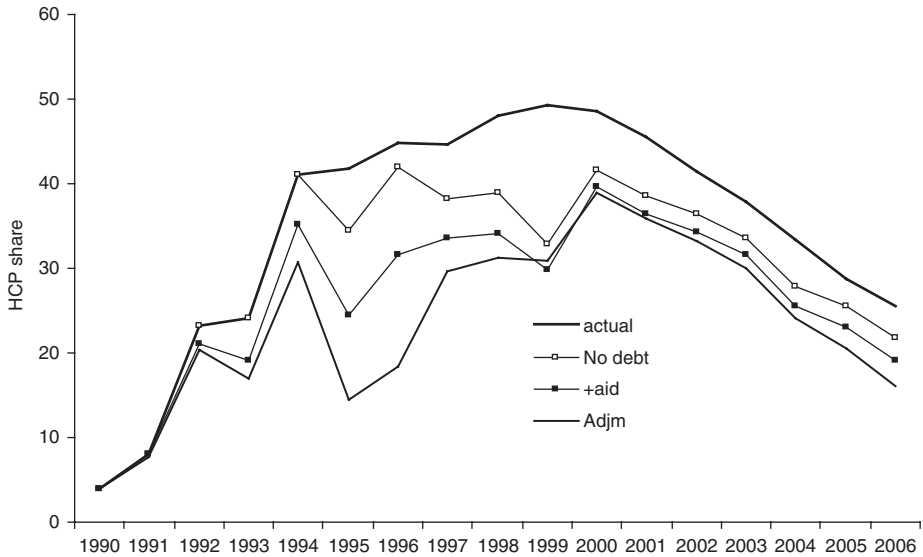

Note: See Table 2 for low income status.

Source: EBRD (1995–2000).

These obvious relationships combined to undermine the health of a large portion of the Moldovan population. This section investigates these effects and links them to the counterfactual calculations of per capita income.

The relationship between the portion of the population in poverty and per capita income is determined by the distribution of income in the vicinity of the poverty line. The higher per capita income for Moldova in the counterfactual scenarios would reduce poverty if the income effect were not cancelled by a negative distribution effect. As a practical matter, it is not possible to incorporate distributional effects into the hypothetical scenarios. Headcount poverty rates for the counterfactuals are calculated on the assumption that distribution near the poverty line remained unchanged during 1990–2006. Given the large changes in income per head, this implicitly assumes a continuous and well-behaved distribution function. Specifically, it is assumed that the elasticity of the number of people below the poverty line with respect to per capita income is slightly more than one in absolute value.<sup>22</sup>

Calculating scenarios on these restrictive assumptions yields the conclusion that during the second half of the 1990s, poverty would have been 8 percentage points lower had there been no debt service to pay (about 300,000 people), 15 points lower with no debt service and ODA (over 500,000 people) and 20 points lower when the multiplier effect is included (750,000 people). During 2000–6, with the economy in its long delayed recovery, the debt and ODA effects remained strong. The absence of debt on non-concessionary terms (low income status) would alone have allowed Moldova to achieve the Millennium goal for reducing extreme poverty (see Figure 3).

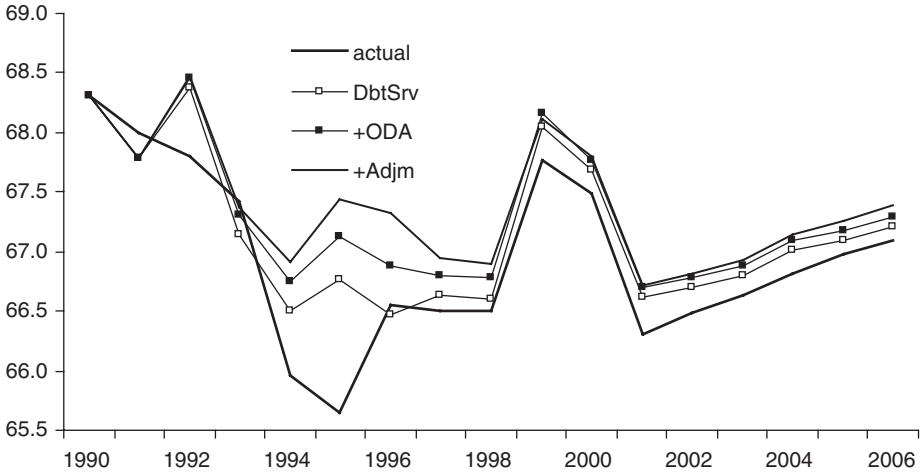

**Figure 3.** Counterfactual headcount poverty in Moldova, 1990–2006

Notes: Household surveys reported national headcount poverty rates of 45% in 1997 and 49% in 2000. A joint IMF and World Bank publication reported higher poverty levels (IMF and World Bank, 2004: 27). For per capita incomes of 540 and 500, respectively, this gives an elasticity of poverty with respect to per capita income of  $-1.06$ . This elasticity is applied to the World Bank reported PCY ('actual PCY') and the counterfactual values generated by the three scenarios. See Appendix for sources and details of calculations.

Poverty is associated with poor health and shorter life expectancy. In 1990 with a per capita income of US\$1148, life expectancy at birth was 68.3 years in Moldova, 71.8 for women and 65 for men. In 1995, with a per capita income US\$570, life expectancy fell to its lowest, 65.7, with a slightly greater percentage decline for women than men. Other things being equal, life expectancy bears a close relationship to per capita income. For Moldova, the relationship would be even closer if one could control for the distribution of income. Figure 4 uses the counterfactual per capita incomes to calculate counterfactual life expectancies, derived from a regression exercise using Moldovan data. The largest differences are for 1994–6, when the counterfactuals calculate a gain in life expectancy between one and two years.

Through the 1990s and 2000s Moldova bore the heavy burden of *faux* middle income status, which lowered per capita income. As a result, more Moldovans fell into poverty than otherwise would have been the case, and on average Moldovans lived shorter lives. Unlike every other transition country in Europe or Central Asia, the Moldovan economy did not recover in the late 1990s; indeed, *in 1999 income per capita was the lowest for the entire decade*. As discussed in the previous section, the failure to recover was a direct result of Moldova's indebtedness-generated financial vulnerability to the Russian crisis of 1998. Via fiscal adjustment, that crisis would lead to a near-collapse in social expenditures.

**Figure 4. Actual and counterfactual life expectancy in Moldova, 1990–2006**

Notes: The variable is life expectancy at birth, average for males and females.

Actual is from *World Development Indicators 2003*, and the others calculated using the counterfactual per capita incomes and life expectancy from the following regression:

$$\ln(\text{LE}) = 3.972 + .035(\ln\text{PCY}) + .018\text{D}$$

[.00]    [.00]            [.00]

d.f. = 9, Adjusted  $R^2 = .733$ ,  $F$ -statistic = 12.93 (.00)

Numbers in brackets give the probably that the coefficient is zero and that the overall relationship is random.

Legend: Debt service is the counterfactual calculation using the regression, and per capita GDP assuming all debt service was used for domestic expenditure.

+ODA adds the difference between ODA for Moldova and low income countries of the former Soviet Union.

+Adj m is the counterfactual that adjusts the multiplier for shift from private to public expenditure.

Sources: See Appendix.

### 5. Deficits and social expenditure

The importance of the link between middle income status and the Russian financial crisis, via the debt vulnerability of Moldova, appears clearly in an analysis of government expenditure.<sup>23</sup> Table 4 shows that despite a fall in per capita income of 45% from 1991 to 1997, social expenditure fell by less than 20%. However, the Russian crisis provoked a public expenditure catastrophe, far worse than what occurred immediately after independence.

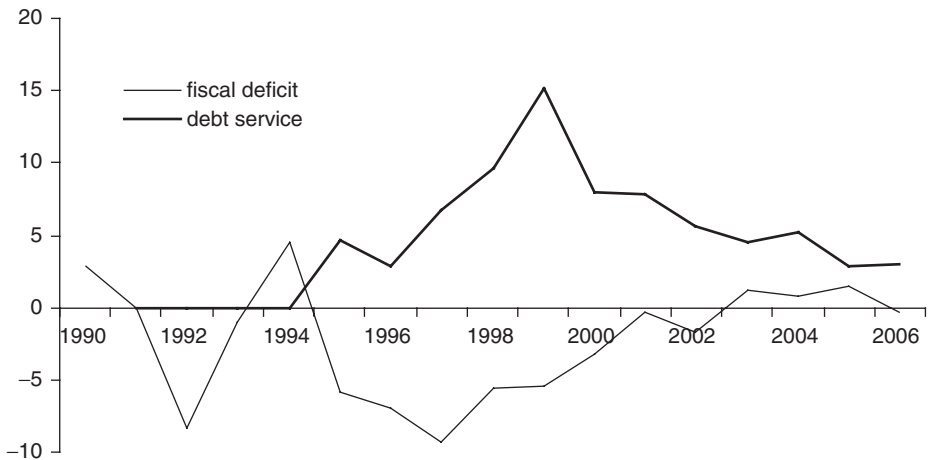

In 1997, the year before the Russian crisis, Moldova’s debt service increased sharply, from 3% to 7% of GDP, and would not fall to 3% again until 2005 (see Figure 5). In 1998, the year of the Russian financial collapse, debt service rose to 10%, then 15% in 1999, when it reached 80% of central government revenues (IMF and World Bank, 2004: 7). This can be compared to the fiscal deficit. As for other transition countries, Moldova suffered a severe revenue collapse soon after dismantling the central planning system. This collapse caused a fiscal deficit of 8% of GDP in 1992. The government quickly brought this down with expenditure reduction, to 1% in 1993, and over-adjusted to run a

2006	742	294	91	31	61

Notes: The numbers are estimated by applying reported percentages to the World Bank per capita income statistics.

Sources: See Appendix.

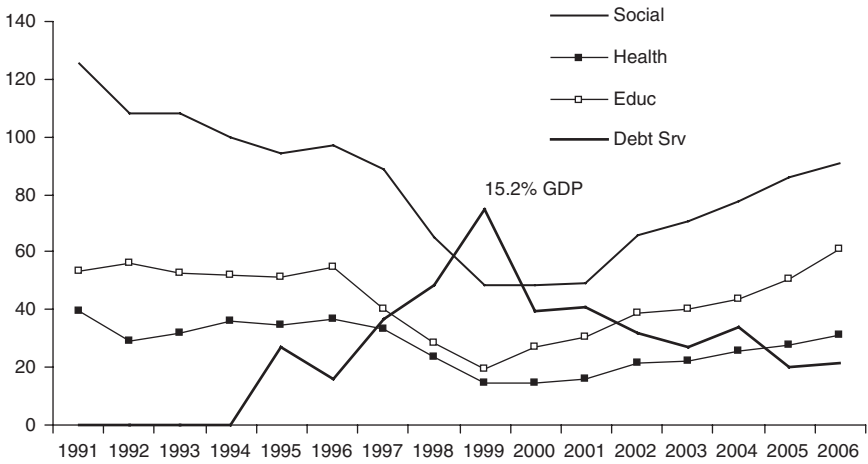

**Figure 5.** Debt service and the fiscal deficit as percentage of GDP, 1990–2006

Source: IMF (see Appendix).

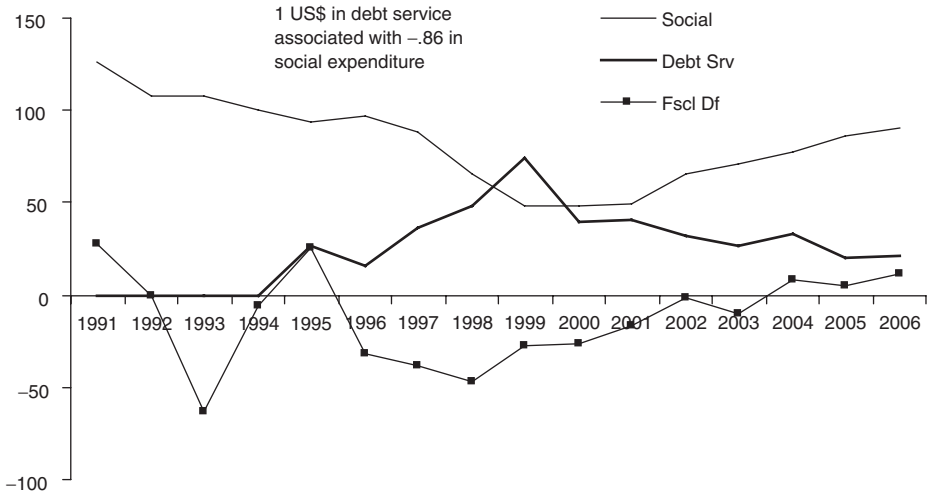

surplus of 5% of GDP in 1994.<sup>24</sup> Debt service brought on a second fiscal crisis during 1995–9, during which the fiscal deficit averaged over 6% of GDP. However, net of debt service, the fiscal balance was 1% in surplus for these years, with a massive shift from –3% in 1997 to +10% in 1999.

This extraordinary fiscal adjustment, 13 percentage points of GDP in two years, was largely the result of severe reductions in expenditure, by 10 percentage points, especially social expenditure.<sup>25</sup> It is beyond controversy that this adjustment, overseen by the IMF, resulted from the requirements of debt service – debt service created by Moldova’s designation to middle income status at the beginning of the 1990s. This deficit reduction, which the IMF lauded as ‘impressive and unprecedented’, had a devastating impact on social expenditures. As Table 4 shows, health expenditure per capita, in 1997 still 97% of its 1991 level, dropped to two-thirds of that level in 1998, and to 40% of it in 1999.<sup>26</sup> The IMF seemed to view the reduction in health expenditure favourably: ‘the bulk of the [expenditure] reduction was concentrated in the bloated health care and education sectors’ (IMF, 2001: 15). Concrete measures included the closure of 75% of hospitals (from 253 to 65), which the World Bank described as ‘progress’.<sup>27</sup> This progress is placed in perspective by a Department for International Development (DFID) briefing paper that reported deteriorations in several health indicators from 1998 to 2000.<sup>28</sup> Figures 6 and 7 show the close relationship between social expenditures and debt service. While the relationship is not contested, indeed, as noted by the IMF (2001: 12–15), the de facto trade-off is striking. In Figure 7, the correlation between the fiscal deficit and debt service is obvious, and after 1994 a \$1 increase in debt service was associated with a fall in social expenditure of 86 cents (constant US dollars of 1995).

The foregoing discussion should not be interpreted as suggesting that reduction of a large fiscal deficit was unnecessary, in Moldova or elsewhere. The point of the discussion is that had Moldova been designated as low income in the early 1990s there would

**Figure 6.** Per capita public expenditure by type, 1991–2006 (constant 1997 US\$)  
Source: IMF (see Appendix).

**Figure 7.** Fiscal deficit, debt service and social expenditure per capita, 1991–2006

Notes: For 1994–2006, the simple correlation between social expenditure and debt service is:

$$[\text{social expenditure per capita}] = 103.49 - .86[\text{debt service per capita}]$$

(.00)      (.00)

Adjusted  $R^2 = .51$ ,  $F$ -statistic @ .00, d.f. = 10

have been a deficit immediately after independence, but not in the second half of the 1990s. The massive fiscal adjustment during 1998–9 would not have been necessary. Assigning middle income status to Moldova and maintaining that designation through almost all of the 1990s resulted in a massive burden of debt service, a burden made worse by the output-depressing impact of the Russian financial crisis, an impact itself fostered by the non-concessionary debt. Public expenditure which could have improved the health and education of Moldovans and supported pensions to the elderly went to service that non-concessionary debt.

## 6. Summary and conclusion

For all Eastern European and Central Asian countries the transition to a market-regulated system was costly in terms of human welfare. Life expectancies fell and incomes declined sharply. The cost of the transition was especially severe in Moldova. A substantial portion of that cost can be attributed to one administrative decision by the World Bank, middle income status rather than low income status. Considering the alternative, a low income Moldova in the mid-1990s, is not a far-fetched counterfactual; countries in comparable circumstances were so designated as early as 1994.

There would seem a clear case for multilateral compensation to the government of Moldova, though that issue lies beyond the scope of this study.<sup>29</sup> If the case of Moldova carries a general lesson, it is that the dichotomy between low and middle income status is not a sound basis for multilateral lending or bilateral development assistance. In

practice, countries above but close to the income borderline between the two categories frequently receive a 'blend' of IDA and IBRD terms for their borrowing. This practice perpetuates the arbitrariness in slightly diluted form.

The dichotomy suffers from several obvious defects. First, it is completely arbitrary, for there is no theoretical basis for such a distinction. Second, it is recognized that the lower the level of development of a country the greater are the potential measurement errors in calculating its national income.<sup>30</sup> For a few countries, Moldova included, even the size of the resident population is uncertain.<sup>31</sup> Finally, it was clear in 1990 that Moldova was one of the poorest countries in Europe, if not the poorest, its measured per capita income notwithstanding. Had the multilaterals based their lending and bilaterals their development assistance on this obvious inference, Moldova's transition would have had a much lower human cost, and its subsequent recovery would have begun several years earlier.

### Acknowledgements

This study was originally published as working paper of the International Poverty Centre, Brasilia, Brasil. The author wishes to thank the many Moldovans who inspired and commented on this paper, including government officials who preferred not to be named. Special thanks go to Nina Orlova of the Swedish International Development Agency (Chisinau), Per Ronnas of Sida (Stockholm) and Rutger Palmstierna of Macro Intelligence (Lidingö, Sweden).

### Funding

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

### Notes

1. From World Bank (1999: 251), a document to which we refer below:

For operational and analytical purposes, the World Bank's main criterion for classifying economies is gross national product (GNP) per capita. Every economy is classified as low income, middle income (subdivided into lower-middle and upper-middle), or high income.

In 2007 the dividing line between low and middle income status was US\$1025. See [web.worldbank.org/WBSITE/EXTERNAL/EXTABOUTUS/IDA/](http://web.worldbank.org/WBSITE/EXTERNAL/EXTABOUTUS/IDA/).

2. Among the first agencies to focus their grants almost exclusively on low income countries was the Swedish International Development Agency. By the turn of the century it became common practice.
3. IBRD (International Bank for Reconstruction and Development) terms can be found at: [web.worldbank.org/servlets/ECR?contentMDK=20066287&contTypePK=214251&folderPK=112519&sitePK=210385&callCR=true](http://web.worldbank.org/servlets/ECR?contentMDK=20066287&contTypePK=214251&folderPK=112519&sitePK=210385&callCR=true), and IDA terms at: [siteresources.worldbank.org/IDA/Resources/IDATerms07.pdf](http://siteresources.worldbank.org/IDA/Resources/IDATerms07.pdf).
4. The procedure for estimation is found at World Bank (1992: 12ff.). See also the contemporary World Bank Working Paper by Ahmad (1992).
5. The lowest was by Bolotin (1992). The World Bank research paper comments:

... little is known about [Bolotin's] sources and methods. Bolotin describes his work as a PPP study and his FSU-US relative in GNP per capita level parallels that inferred from WDI-PP. (World Bank, 1992: 22)

6. Throughout this article statistics for Moldova are exclusive of Transnistre, a small section of the country that declared autonomy in the early 1990s. It subsequently was outside the administrative control of the government in Chisinau. The population statistics used in calculations exclude Transnistre.
7. By 1996 all the major international agencies reported almost the same annual growth rates, though they may have reported different per capita incomes. See EBRD's *Transition Reports* and IMF (1998, 1999, 2001, 2005).
8. A schedule of IMF lending to Moldova is given on the IMF website, at: [imf.org/external/np/fin/tad/exfin2.aspx?memberKey1=672&date1key=2007-07-05](http://imf.org/external/np/fin/tad/exfin2.aspx?memberKey1=672&date1key=2007-07-05).
9. The World Bank's lending policies towards the transition countries came under criticism from the organization's evaluations department:

Effectiveness was limited by an initial underestimation of the need to focus on poverty alleviation and good governance and the use of rapid privatization to promote private sector development (PSD) without a supporting legal and institutional framework. Lending was based on the expectation of a short, shallow transition recession; the prolonged recession in some CIS countries led to the accumulation of significant levels of indebtedness. (World Bank, OED, 2004: x).

Assessment of the conditionalities attached to World Bank lending to Moldova lie beyond the scope of this study. World Bank lending is reported at: [lnweb18.worldbank.org/eca/eca.nsf/Countries/Moldova/6D77BD6402E0F21D85256C2500626BB0?](http://lnweb18.worldbank.org/eca/eca.nsf/Countries/Moldova/6D77BD6402E0F21D85256C2500626BB0?)

10. I thank staff at the EBRD for providing me with a full listing of its operations with Moldova.
11. An IMF and World Bank joint report in 2004 commented on concessional lending to Moldova:

Concessionality for Armenia and Moldova dwindles, but for different reasons, as Armenia graduates and Moldova remains cut-off from concessional assistance. It is hoped, though, that Moldova will resume an acceptable adjustment path sufficient to attract international support and avoid the pessimistic scenario portrayed here. (IMF and World Bank, 2004: 18)

Nonetheless, later in the report it stressed Moldova's need for concessional finance,

Highly concessional stock-of-debt operations in the Kyrgyz Republic, Tajikistan, and Georgia and Moldova (once performance has been reestablished in the latter two countries) are key to attaining debt sustainability. (IMF and World Bank, 2004: 18)

12. There were three consecutive biannual WDRs: 1998/1999 (none for 1998 alone), 1999/2000 and 2000/2001.
13. See for example, EBRD, *Transition Report 2000*.
14. For WDRs 1993–7 countries were listed in ascending order of per capita income. From the 1998/1999 WDR countries were listed in alphabetical order, with the benchmark reported in notes, and a table provided at the end of each report listing countries by category.
15. The dates for designation of low income status were given in a joint IMF and World Bank report:

The World Bank granted IDA-only status to five highly-indebted countries of the CIS-7 group (Armenia, Georgia, Kyrgyz Republic, Moldova and Tajikistan) in 2000. Shortly thereafter, Azerbaijan and Uzbekistan also obtained access to IDA resources. (IMF and World Bank, 2004: 14)

16. For an analysis and chronology of Moldova's debt accumulation and restructuring, see the report to the Swedish International Development Agency written by the chief consultant to the Moldovan government (Palmstierna, 2007).

17. A World Bank web page states,

Since 1993, the World Bank has financed 23 operations in Moldova for a total commitment of US\$592.01 million. This includes five adjustment loans (US\$235 million), and 18 investment operations (US\$341.5 million). Of the investment operations, 9 are IBRD loans, 13 are IDA credits, and one is an IDA grant. ([Inweb18.worldbank.org/eca/eca.nsf/Countries/Moldova/6D77BD6402E0F21D85256C2500626BB0?OpenDocument](http://web18.worldbank.org/eca/eca.nsf/Countries/Moldova/6D77BD6402E0F21D85256C2500626BB0?OpenDocument))

The first substantial IDA loan was in September 1997, by which time the Moldovan government had borrowed US\$360 million on IBRD terms (almost US\$100 per capita), sufficient to qualify Moldova as heavily indebted under subsequent HIPC criteria.

18. This is consistent with the conclusion reached in an IMF working paper on the lending by 'multilaterals' to the countries of the former Soviet Union:

Third, over-optimism by multilaterals contributed to the high debt levels. If external financial assistance, which was needed because of high social costs of the transition, had come in the form of grants in the first two or three years of the transition, the debt burden would have been lower and sustainable. (Helbling et al., 2004: Abstract)

The study included seven countries: Armenia, Azerbaijan, Georgia, Kyrgyz Republic, Moldova, Tajikistan and Uzbekistan. An analysis of Moldova's debt position in the early 2000s is found in IMF and World Bank (2001).

19. This was recognized explicitly for Moldova in an IMF and World Bank report,

In 1999, the ratios of debt service due to exports remained below 25 percent for all countries except Moldova, which has significant debt on commercial terms. Debt service due accounted for over 80 percent of central government revenues in Moldova ... (IMF and World Bank, 2004: 7)

20. Of the countries in the table, only petroleum exporting Turkmenistan did not receive low income status before Moldova.
21. The hypothesis was tested that the percentage deviations from 1997 during 1998–2000 were associated with low income status and petroleum exports. For low income status, the binary variable takes the value of 1 for the years in which the country was listed as low income by the World Bank. The other hypothesis assigns the value of 1 to the petroleum exporting countries Azerbaijan and Turkmenistan. The statistics are:

$$Dv_{1997} = -7.84 + 13.60[LYS] + 14.37[Petrol]$$

(ns)      (.00)      (.00)

$$\text{Adjusted } R^2 = .60, F = 15.19 (.00), \text{ d.f.} = 18$$

Where  $Dv_{1997}$  is the deviation of per capita GDP from the 1997 value, LYS is low income status (equal to 0 or 1), and Petrol is whether a country exported petroleum (0 or 1). The constant term is not significant at 5% probability, and the binary variables are both significant at lower than 1% probability, as is the  $F$ -statistic.

22. The elasticity is  $[(\Delta H/\Delta Y)(Y/H)]$ , where  $H$  is the number of people below the poverty line and  $Y$  is per capita income. This is not the same as the elasticity of the poverty share with respect to per capita income. The elasticity is  $-1.06$ , which is the value obtained by comparing the household surveys of 1997 and 2000 (for details see Weeks et al., 2005: Ch. 4, and especially the annex to that chapter).
23. An IMF report stressed the damaging effect of the Russian crisis:

When the Russian crisis hit in August 1998, output declined [in Moldova], macroeconomic imbalances surged and the financial situation became fragile. (IMF, 2001: 6)

## 24. The IMF commented,

Following the collapse of the Soviet Union and Moldova's independence in 1991, output dropped sharply and inflation soared, but through mid-1998, substantial progress was made in financial and macroeconomic stabilization... (IMF, 2001: 6)

## 25. The IMF described the process as follows: 'The 1999 fiscal adjustment was approximately 6 percent of GDP; it came largely through rationalization of public expenditures, notably reducing inefficiency in the social sectors' (IMF, 2001: 6). The quoted 6% refers to the budget inclusive of external debt service.

## 26. A World Bank report in 2003 referred to 'dramatic reductions ... brought on by the 1998 fiscal crisis' (World Bank, 2003a: v). According to Table 5 in the report, health expenditure fell in real terms by 32% in 1998 and 35% in 1999 (World Bank, 2003a: 16). A diagram on the same page indicates per capita expenditures lower than reported in Table 4 in this study.

## 27. The exact quotation is, 'Despite this progress, there is a significant unfinished agenda' (World Bank, 2003a: 1).

## 28. Of 10 indicators, four improved: maternal deaths, malignant neoplasms, 'external causes of death' and reported HIV cases. Those that worsened were: life expectancy, perinatal mortality rate, infant mortality rate, diseases of the circulatory system, and new TB cases (DFID UK, 2004: 2).

## 29. As late as 2004 the World Bank excluded Moldova from any debt relief, including changing the terms of its 1990s debt:

Moldova's earlier classification as a moderate debt distress risk country qualified it for 50 percent grants for those operations approved in FY06. The transition away from CAS lending scenarios has proved to be challenging in both reaching a shared understanding with the authorities, as well as for timely planning of lending operations.

... Given the improved debt situation, Moldova no longer qualifies for the 50 percent grant element from FY07. (World Bank IDA, 2004: 4, 7-8)

The 'improved debt situation' resulted from negotiations by the government of Moldova with its creditors, with limited World Bank involvement (see Palmstierna, 2007).

## 30. To take but one reason, the more underdeveloped a country the larger is its portion of non-marketed output.

## 31. Per capita income is not calculated directly, but by estimating national income and dividing by the population. Estimates of migration from Moldova vary greatly (see Weeks et al., 2005: Ch. 5).

## Résumé

### *Erreur sur la personne: Moldova, un pays un pays 'à revenu intermédiaire' et les conséquences*

La République de Moldova, nouvellement indépendante, a rejoint la Banque mondiale et le FMI en 1992. La Banque mondiale la désignée comme un pays 'à revenu intermédiaire', un statut qu'elle a conservé pour le crédit Bretton Woods jusqu'en 1997. La désignation 'à revenu intermédiaire' a laissé entendre que le gouvernement moldave n'était pas éligible à un financement concessionnel par des organismes de développement multilatéraux et les organismes bilatéraux plus importants. Après avoir démontré que l'attribution à la Moldavie du statut à revenu intermédiaire a été une erreur, cet article étudie les conséquences. Une procédure simple est utilisée pour calculer des scénarios

hypothétiques dans lesquelles la Moldavie a été attribuée le statut de faible revenu dans le début des années 1990. Les scénarios hypothétiques suggèrent que les coûts de développement et de l'assistance publique découlant de l'erreur étaient extrêmement élevés: une chute beaucoup plus importante du revenu par habitant qui autrement n'aurait pas été le cas, avec des augmentations liées à la pauvreté des effectifs et à l'espérance de vie inférieure. Si la Moldavie avait été désignée, un pays à faible revenu dans le début des années 1990, au milieu des années 2000, elle serait devenue un pays à revenu intermédiaire au lieu du plus pauvre en Europe.

## Resumen

### *Identidad errónea: La Moldova de 'ingresos medios' y las consecuencias*

La recientemente declarada independiente República de Moldova se unió al Banco Mundial y al FMI en 1992. El Banco Mundial la designó un país 'de ingresos medios', un estatus que retuvo para los créditos de Bretton Woods hasta 1997. La designación de ingresos medios implicaba que el gobierno de Moldova no fuera apto para las finanzas concesionarias de las importantes agencias de desarrollo bilateral y multilateral. Después de demostrar que el asignar el estatus de ingresos medios a Moldova fuera un error, este artículo investiga las consecuencias. Se utiliza un procedimiento simple para calcular escenarios contrafácticos concernientes a que a Moldova le fuera asignado el estatus de ingresos bajos a principios de los años noventa. Los escenarios contrafácticos sugieren que los costes de desarrollo y de bienestar del error fueron muy altos: una caída mucho mayor en ingresos *per capita* que, de otra manera, hubiera sido el caso, con incrementos asociados al recuento de personas en estado de pobreza y esperanza de vida más baja. Si Moldova hubiera sido designada como país de bajos ingresos a principios de los noventa, a mediados de los años 2000, habría sido un país de ingresos medios en lugar de ser el más pobre de Europa.

## Biographical note

John Weeks is Professor Emeritus of the University of London and was director of the Centre for Development Policy and Research of the School of Oriental and African Studies. He was the team leader for a United Nations Development Programme and International Labour Organization report on Moldova in 2005. He is author of many articles and books on theory and policy for developing countries.

## Appendix: Constructing counterfactuals

### *1. Statistical sources*

As explained in the next section of this appendix, the counterfactuals in this study are based on the national income identity. Constructing a consistent national income series for Moldova is tedious, because the country did not adopt its own currency until 1993

(the *leu*, spelled *lei* in some sources). The National Bank of Moldova provides a time series on GDP for 1995–2006, and other time series are found in EBRD Transition Reports (various issues) beginning in 1991, and IMF reports (1996, 1998, 1999, 2001, 2005, 2006a) beginning in 1993. Statistics for the late 1980s and early 1990s in current and constant Russian roubles are given in World Bank sources (1993a, 1994b, 1995a, 1996a). Statistics on the shares of the major components of GDP are found in the same IMF and World Bank sources. Prior to 1995, we have calculated shares from the World Bank Statistical Handbooks (World Bank, 1993a, 1994b, 1995a, 1996a).

The GDP growth rates for per capita income are similar in all sources. These are applied to the per capita income statistic in the *World Development Report 1997*, which drastically revised Moldova's income per capita. GDP is obtained by multiply by the population. The calculations use the population numbers implied by dividing GDP in *leu* by GDP per capita in *leu*, both from the National Bank of Moldova macroeconomic statistics (NBM website). The debt service statistics are from the National Bank of Moldova, and are also reported in the various IMF country reports.

There are no statistics on the share of private investment in GDP. This ratio was calculated by assuming inventory change to be zero, which implies (all symbols are shares of GDP):

$$I = S - [(G - T) + (X - M)], \text{ where } G, T, X \text{ and } M \text{ are known.}$$

Government expenditure is net of transfers to various special funds if the actual expenditure for the services in question is included under other budget items (such as pension payments). Government expenditure includes both current and capital outlays.

## 2. Counterfactuals

The counterfactual scenarios are calculated using the basic national income identity and the distinction between induced and exogenous variables. By definition,

$$\begin{aligned} Y &= C + I + G + (X - M) + \Delta \text{inv} \\ Y_d &= Y - T, T = tY \\ C &= a(1 - t)Y \\ M &= nY \end{aligned}$$

Variables (measured in constant US dollars of 1995):

- Y = national income
- C = private consumption
- I = investment
- G = government expenditure
- X = exports
- M = imports
- $\Delta \text{inv}$  = inventory change
- T = government revenue (taxes and fees, but not external grants)
- $Y_d$  = disposable income

Parameters:

a = marginal propensity to consume, assumed equal to the average

t = marginal propensity to tax, assumed equal to the average

n = marginal propensity to import, assumed equal to the average

If  $\Delta \text{inv} = 0$ , and  $\beta$  is the multiplier, then,

$$Y = (I + G + X)\beta$$

The calculations do not include any exchange rate effects, so each period's actual export value is assumed to hold in the counterfactual. For simplicity, interest rate and other influences on investment are ignored, so that each period's actual investment applies in the counterfactual. Government expenditure is the only autonomous variable that changes, and is introduced as a share of GDP ( $G/Y = g$ ). This allows for three calculations, two of which are counterfactual scenarios,

$g_1 = [G(\text{NDS})_t]/\text{GDP}$  = government expenditure with debt service

$g_2 = [G(\text{NDS})_t + \text{DS}]/\text{GDP}$  = government expenditure with debt service converted to domestic expenditure

$g_3 = [G(\text{NDS})_t + \text{DS} + \text{ODA}]/\text{GDP}$  = government expenditure as for  $g_2$  and ODA

$$Y = (I + X)\beta(1 - \beta g_i)$$

Where I and X are in US\$ of 1995, and  $g_i$  equals  $g_1$ ,  $g_2$ , or  $g_3$ .

**Table A1.** Official development assistance to countries of the former Soviet Union, share in GDP, 1991–9

	1991	1992	1993	1994	1995	1996	1997	1998	1999

3. Adjusted multiplier																	

Notes: g1 is government expenditure net of debt service, which is actual domestic expenditure.

g2 is government expenditure including debt service, used for the counterfactual 1.

g3 is government expenditure including debt service plus ODA/GDP (see next note).

<sup>a</sup>ODA/GDP is the difference between what Moldova actually received in concessional finance and the average for low income former Soviet countries. See Table A1.

<sup>b</sup>Adjusted is the multiplier adjusted for the switch of expenditure from the private to the public sector. See discussion in the text and this Appendix.
